# Addendum: comparable baskets and OffMenu integration

Research proposal · 13 October 2026 · Applies to the existing 249-entry register

Use a common measurement contract for every basket: preserve the original quantity and population, convert foods to a documented edible state, attach compatible composition evidence, and report nutrients and food-group amounts using the same denominators. Product and menu qualification is a separate evidence layer.

Recommended comparison cards: protein g, total and saturated fat g, fibre g, sodium mg, vitamin C mg, fruit g and non-starchy vegetable g per 1,000 kcal; show basket totals and person-day values alongside them where documented. Add a clearly labelled 2,000-kcal analytical equivalent for easy comparison.

This addendum defines the calculation and integration contract. It does not claim that OffMenu software, APIs or supplier connections have been implemented or verified. The research register has been transformed; product code has not changed.

| What is now structured | Coverage |
|---|---|
| ISO country/territory records | 249, including special provisioning contexts |
| Editorial demo food lines | 2,523 across 242 entries |
| Separate published food-example lines | 707; partial source evidence, not complete official baskets |
| Food identity candidates | 352 distinct source labels → 337 provisional concepts in 17 groups |
| Complete quantitative country comparisons | 0: quantities, edible states and composition matches remain unresolved |

Every original food label is retained. Each line now has a proposed concept ID, provisional food group, stable country-line ID and explicit missing inputs. All 249 records have comparison-readiness fields; unknown nutrient amounts remain null.

Seven entries have no ordinary household default: AQ, BV, GS, HM, IO, TF and UM. They remain in the register with a special provisioning route. No national household diet is invented for them.

# 1. One measurement contract, several useful views

A denominator answers a specific question. Display its unit, food state, basket version and evidence track beside every comparison. The following are proposed OffMenu views, not claims that each national source already supplies them.

| View | Calculation / interpretation | Required basis |
|---|---|---|
| Basket total | Sum edible nutrients and food-group grams across the complete basket. | Defined membership and quantities; do not combine demos with partial published examples. |
| Per person per day | Total ÷ documented person-days. | Household composition and period; acquisition is not actual intake. |
| Per 100 g edible | 100 × total ÷ total edible mass. | Same raw/cooked basis; water and beverages affect density. |
| Per 1,000 kcal | 1,000 × total ÷ total basket energy. | Complete, compatible energy; undefined at zero energy. Main density comparison. |
| 2,000-kcal equivalent | 2 × the per-1,000-kcal amount. | Analytical scaling only. Not an assumed personal energy requirement. |
| Per serving / meal | Recipe total × serving fraction. | Measured serving mass or defensible portion fraction and recipe version. |
| % of reference | 100 × person-day amount ÷ named reference amount. | Same reference system, version, nutrient definition and life-stage profile. |

Person-days = Σ(persons in a population segment × days covered). Preserve infants, children, adults, pregnancy and lactation where relevant. An energy-based adult-equivalent factor cannot be reused as the requirement factor for every vitamin or mineral.

A shared analytical reference profile must be selected and versioned before %reference comparisons are enabled. Store local reference values separately. Reference coverage is descriptive and does not diagnose adequacy or deficiency.

# 2. Core nutrient metrics

Keep source nutrient names, codes, units and derivation methods, then map to compatible internal components. The JSON companion defines 45 nutrient fields. These internal identifiers are proposals, not invented FAO or USDA codes. N01, N06

| Metric family | Canonical amount | Comparison rule |
|---|---|---|
| Energy | kcal and kJ | Metabolisable energy with source method; 1 kcal = 4.184 kJ. |
| Protein | g | Retain nitrogen conversion factor/method. Grams alone do not measure protein quality or digestibility. |
| Fat | g total; saturated, mono/polyunsaturated, trans separately | Subsets must not be added again to total fat. Keep ALA, EPA and DHA separate. |
| Carbohydrate | g available and g by difference separately | Do not silently combine definitions or subtract fibre twice. |
| Sugars | g total; added; free separately | Total sugar does not reveal added or free sugar. Recipe/definition evidence required. |
| Fibre | g | Record analytical method and component coverage. |
| Sodium / salt | mg sodium; g salt equivalent | Derived salt equivalent = sodium mg × 2.5 / 1,000. Preserve declared salt separately. |
| Water / alcohol / cholesterol | g / g / mg | Retain where available; water is essential to interpreting mass-based comparisons. |

Report macro energy share only with a stated, compatible energy-factor method. For example, 100 × 9 × fat_g / energy_kcal is an explicitly labelled general-factor estimate, not a universally interchangeable label value. Do not force macro shares to total 100% when energy definitions differ.

Use protein g/1,000 kcal and fat g/1,000 kcal for density; use grams/person/day for documented acquisition or consumption. A higher value is not automatically a better basket.

# 3. Vitamins and minerals: comparable definitions

At minimum expose vitamin C, vitamin A, vitamin D, vitamin B12, folate, calcium, iron, zinc, iodine and potassium, with missingness shown separately for each. Extend to B1, B2, B6, niacin, E, K, magnesium, phosphorus and selenium when evidence supports it. N01, N06

| Metric | Unit / definition | Required distinction |
|---|---|---|
| Vitamin C | mg | Ascorbic acid only versus total vitamin C; preparation and nutrient-retention basis. |
| Vitamin A | µg RAE; µg RE in separate fields | RAE, RE and IU are not interchangeable labels; component-specific conversion needed. |
| Vitamin D | µg | Specify included forms; preserve fortification and formulation evidence. |
| Vitamin E / K | mg / µg | Specify alpha-tocopherol versus alpha-TE; K1/K2/total coverage. |
| Folate / B12 | µg food folate, folic acid, DFE; µg B12 | DFE needs a documented conversion convention. Missing fortification data cannot be assumed. |
| B1, B2, B6, niacin | mg; niacin equivalents separately | Keep chemical amount and biological-equivalent expressions distinct. |
| Calcium, iron, zinc, potassium, magnesium, phosphorus | mg | Measured content does not establish absorbed dose or bioavailability. |
| Iodine / selenium | µg | Do not infer concentration simply from food name or origin. |

Store original component values and the conversion rule/version. Only aggregate compatible expressions; if conversion inputs are absent, retain parallel series or mark the value unresolved.

Food composition varies with variety, production, processing and sampling. Product label values may be rounded or omit micronutrients. A missing vitamin C declaration is not 0 mg; a rounded label zero is not an analytical zero. N04, N05

# 4. Food groups are quantities, not nutrient names

Use edible grams and edible-mass shares, plus grams/person/day and grams/1,000 kcal when those denominators exist. Food-group IDs and allocation rules must have a version. The following is the proposed common reporting convention; local dietary-guideline views may use different definitions.

| Group measure | Included / excluded rule |
|---|---|
| Fruit g | Report whole/fresh/frozen, canned and dried fruit separately. Juice is a separate measure. No automatic fresh-equivalent multiplier. Avocado is fruit in this convention. |
| Non-starchy vegetables g | Culinary vegetables including tomato and identified immature green peas/beans. Exclude dry pulses, starchy roots and cooking plantains. |
| Other starchy staples g | Potato, cassava, taro, yam, cooking banana, plantain, breadfruit and sago; tracked separately from headline vegetables. |
| Pulses/soy; nuts/seeds g | Separate groups. Do not count the same mass again as vegetables or protein grams. Coconut is in nuts/seeds for this convention, not an allergen classification. |
| Cereal foods; wholegrain content | Food-group mass is not automatically grain-equivalent mass. Wholegrain fractions require ingredients or a defined conversion method. |
| Animal foods; dairy; oils/fats | Use separate meat, poultry, seafood, eggs and dairy fields. 100 g chicken is not 100 g protein; 100 g butter is not 100 g fat. |
| Composite foods and drinks | Allocate only evidenced ingredient fractions; keep unallocated mass visible. Added water must not become fruit/vegetable credit. |

For a decomposed dish, group_g = Σ(final edible mass_i × evidenced group fraction_i). Fractions must be non-overlapping and sum to at most 1; retain an unallocated remainder. Ingredient-basis grams and final-dish grams are separate metrics, not interchangeable.

The current 17-group assignments are provisional routing classes. Labels such as “peas”, “corn”, “milk or fortified alternative” and combined categories remain ambiguous. Counts of lines in a group are not mass percentages and must never be displayed as nutritional composition.

# 5. Quantity, cooking and recipe normalisation

Preserve the original amount and unit. Create a reproducible conversion chain to edible grams; never overwrite source quantities. Match the composition record to the actual state, preservation, edible portion and fortification. N02, N03

| Step | Calculation / handling |
|---|---|
| Original unit → mass | kg × 1,000; g unchanged. For volume: ml × product/state-specific density in g/ml. For count: count × supported unit mass. No universal 1 ml = 1 g rule. |
| Purchased → edible | Edible raw g = purchased g × edible fraction. Packaging, peel, shell, bone and refuse need explicit treatment. Use drained mass and matching composition where applicable. |
| Matched-state nutrients | Nutrient amount_i = edible g_i × nutrient per 100 g_i / 100. Sum only compatible components. |
| Raw composition → cooked | Retained nutrient = raw edible g × raw per-100-g value / 100 × nutrient-specific retention factor. Cooked g = raw edible g × yield factor, for that defined process. |
| Cooked concentration | Per-100-g cooked = 100 × retained nutrient / cooked g. Track added/removed fat, water and ingredients explicitly. Yield alone does not quantify vitamin loss. |
| Already-cooked composition | Use measured/matched cooked grams directly. Do not apply the same retention or yield correction again. |
| Recipe → shopping | Scale ingredients by portions, subtract usable inventory, map to purchase yield, then round to packs. Retain leftover quantities; pack cost and consumed-food cost differ. |

A cooked-menu route needs recipe version, ingredient quantities, preparation method, final batch yield and actual serving size. Include sauces, cooking oil, toppings and modifiers. A menu name alone is not enough to calculate nutrients.

For powder, concentrate, tea and coffee, distinguish dry/as-sold from reconstituted/as-served composition. Record both preparation instructions and dilution; do not match dry quantities to prepared values.

# 6. Evidence, missing data and reproducibility

Recommended matching order: exact market/product/version evidence; suitable national composition record for the specified food/state; documented recipe calculation; closely matched regional/international generic record; explicit proxy. This is a relevance-based hierarchy, not a guarantee that branded labels are more precise than analytical food data. N02, N04, N05

| Record or check | Proposed requirement |
|---|---|
| Nutrient observation | value, unit, component definition, basis, state, source record/version, method, geography, sample/label date, retrieval date and rights. |
| Value status | Analytical, label-reported, recipe-calculated, generic estimate, imputed, missing, below quantification or rounded zero. Preserve lower/upper bounds where supplied. |
| Coverage by nutrient | Mass coverage = supported mass / complete edible mass. Energy coverage = energy of supported lines / complete energy. Denominators must themselves be known. |
| Partial result | Display “known subtotal”, missing foods and coverage. Do not silently convert missing to zero or scale known rows to 100%. |
| Uncertainty | Retain ranges and proxy sensitivity. Do not manufacture confidence intervals from a single mean or add marginal uncertainty bounds as independent errors. |
| Calculation lineage | Immutable basket, recipe, composition, offer, reference and rule versions; conversion factors; timestamp; reproducible input hash. |

A basket may have complete protein data and incomplete vitamin C data. Publication readiness is metric-specific. Default ranking requires complete quantities, compatible nutrient evidence for every included food, complete energy for energy-normalised views and no material unresolved conflicts.

Estimated values may support a clearly marked modelled comparison if assumptions and sensitivity are disclosed. Keep it separate from source-measured comparisons. If a plausible missing-value or proxy scenario reverses the order, withhold the rank.

# 7. Competitive analysis without false precision

Comparison cohorts must share basket purpose, evidence track, target population, preparation convention, reference period and nutrient definitions. Keep editorial demonstrations, published basic-needs baskets, household acquisition, dietary-intake surveys and national food availability separate. National supply is not observed eating. N08

| Comparison | Required controls |
|---|---|
| Nutritional profile | Show density, person-day quantities where documented, evidence coverage and uncertainty. Use profiles and differences; no default “healthiest country” league table. |
| Country-relative cost | Retain local currency, date, geography, outlet/channel, tax, delivery and promotion conditions. Report consumed-food cost/person-day and cost/1,000 kcal. |
| Common-currency cost | Use date-matched FX for transaction comparisons. PPP-adjusted views must name series, component, reference year and methodology; household-consumption PPP is a broad contextual measure, not a precise food SKU converter. N07 |
| Price versus composition | For pure price competition hold the food specification/quantities constant. For local baskets differing in foods, show composition differences alongside cost. |
| Affordability | Cost/person-day ÷ compatible disposable resources/person-day; define income or budget basis. Do not use GDP/person as a household shopping budget. |
| Supplier / dietary coverage | Share of mass, spend or lines meeting the named requirement. Show pass/fail/unknown/conflict coverage separately; state the denominator. |

Optional cost per 50 g protein measures one objective, not balanced-diet value. Similarly, energy-normalised cost can favour energy-dense foods; pair it with food-group and nutrient profiles.

Compare differences with intervals or sensitivity bands where available. Do not declare a winner from rounding-level differences. Any composite score needs explicit weights, direction, caps, exclusions and a version; do not create one by default. CPI expenditure weights are not edible-mass shares.

# 8. OffMenu integration contract: entities and joins

Use this as a proposed handoff contract for the existing discovery/enrichment work. Names below describe logical records; no actual OffMenu database tables or endpoints were inspected. Preserve stable IDs and explicit many-to-many mappings.

| Record | Minimum fields | Relationship |
|---|---|---|
| basket_definition | basket_id/version; ISO2/subregion; purpose/evidence track; household/period; source/rights | One basket → many separately versioned lines. |
| basket_line / food_concept | line_id; original label; concept; original and edible quantities; state; substitutions | Generic concept is independent of a brand or barcode. |
| composition / observation | composition_record/version; component; per-100-g basis; value/status; provenance | One record → many nutrient observations; retain field-level sources. |
| product_version | product_id; GTIN; market; net/drained mass; formulation/label snapshot; ingredients | Product can match multiple generic concepts; GTIN alone is insufficient. |
| menu_item / recipe | venue/outlet; item/version; modifiers; recipe/version; ingredients; yield; serving | Menu item → selected recipe → ingredient/product quantities. |
| offer / supplier / site | SKU; seller; outlet; market; currency/price/date; supplier/site IDs; availability | Same product can have several offers and suppliers. |
| qualification / evidence | subject; scheme/rule/version; issuer; scope; validity; status; proof; checked date | Claims attach to their actual product, site, entity, menu or lot. |
| comparison_result | basket/version; metric; denominator; value/status; coverage; lineage; calculation version | Rebuild results when any relevant input changes. |

A basket resolves to food concepts, then eligible product versions or menu servings, then current offers. Nutrient calculations consume quantified composition evidence. Dietary and supplier rules evaluate the selected products, recipes and suppliers; they do not attach blindly to the country.

Carry tenant, source licence, attribution, retention and permitted-use metadata throughout. User-provided credentials authorise that user’s access only; they do not establish redistribution rights. Shared catalogues and private imported data need separate permissions.

# 9. Barcodes, menus and substitutions

GS1 identifiers can link trade-item identity and related information; they do not themselves certify nutrition, origin or dietary suitability. GS1 product-change rules are relevant to versioning, and barcode prefixes do not prove where food was produced. N09, N10, N11, N12

| Route | Proposed behaviour |
|---|---|
| Barcode scan | Preserve the scanned string and symbology. Validate applicable GTIN length/check digit; store a canonical GTIN-14 string with leading zeros while retaining original form. Parse GS1 Digital Link/Application Identifiers where supplied. |
| Product match | Resolve market, pack/net/drained size, label/formulation version and observation date. Store lot/expiry separately when available. Multiple matches remain candidates until resolved. |
| Loose or local food | Allow generic concept + retailer SKU/PLU/local ID. Do not fabricate a GTIN for unbarcoded produce or a restaurant dish. |
| Menu match | Use venue, outlet, item/version, portion, modifiers, recipe and preparation evidence. Ingredient/portion unknowns remain visible. Recalculate after any substitution. |
| Mixed provenance | A product’s labelled protein can coexist with an estimated generic vitamin C value, but each retains its own source/status. Never describe the estimate as manufacturer-declared. |
| Substitution engine | Apply required dietary/supplier constraints before preference ranking. Then compare serving function, quantity, nutrients, price and availability; expose why an alternative qualifies. |

A practical basket-line handoff is: country/line ID → food concept and required edible quantity → candidate product/menu version → nutrient observations → offer/supplier → qualification evaluation → selected amount. The original country-source wording and evidence status remain accessible.

Re-evaluate affected results when formulations, recipes, allergens, certificates, recalls or prices change. A recall event needs product/market/lot scope and dates; do not infer that a historical recall covers every product from the same brand.

# 10. Dietary and supplier qualifications

Use pass, fail, unknown, conflict and not_applicable for a specific rule evaluation. “Pass” means supported against that named rule and scope, not universally safe. Missing or expired evidence is not proof that a supplier is unsafe. Allergen declarations, precautionary warnings and dietary claims are separate evidence types. N13

| Qualification family | Evidence needed |
|---|---|
| Allergen / intolerance | Specific ingredient/allergen; contains versus may-contain versus supported absence; market/rule; label/recipe version; preparation/cross-contact controls. Unknown allergy evidence cannot become a suitability pass. |
| Vegan, vegetarian, gluten-free, low-sodium, etc. | Declared or certified claim, applicable definition, ingredients and/or quantitative threshold. Vegan is not proof of freedom from milk/egg cross-contact. Nutrient claims need local rules and serving basis. |
| Halal / kosher / organic / non-GMO | Scheme, certifier, certificate or declaration, products/premises covered, validity and market recognition. Keep kosher subtypes and product versus ingredient certification distinct. |
| Food-safety systems | Legal entity and actual facility; certificate number, programme/version, issuing body, scope, validity and suspension/withdrawal status. Check the scheme register where available. N14, N15 |
| Programme recognition | Record recognised programme/version/scope separately from the individual supplier certificate. GFSI recognition is not a supplier “GFSI certification”. N16 |
| Origin / ownership / sourcing | Separate grown/raised/caught, manufactured, packed, brand owner and ultimate owner; retain dates and supporting records. Do not use the barcode prefix as origin evidence. |

Store regulatory eligibility separately from preference rules. An additive restriction requires jurisdiction, food category, amount/limit, effective date and applicable exception; a global “banned” flag is insufficient. No complete 249-country legal-rule catalogue is claimed here.

Show both qualification coverage and evidence coverage. With a known total mass, pass_mass/total_mass is the supported qualifying share; unknown_mass/total_mass is the gap. Do not quietly exclude unknowns from the denominator. Strict user requirements should block automatic selection until evidence is sufficient.

# 11. Worked comparison: synthetic mini-baskets

These invented profiles demonstrate arithmetic only. They are not real foods, countries, meal plans or composition recommendations. All quantities below are edible grams in a common prepared state; person-day values are deliberately absent.

| Input (per 100 g) | kcal / protein g / fat g / C mg | A g | B g |
|---|---|---|---|
| Cooked starch | 130 / 2.5 / 0.3 / 0 | 300 | 200 |
| Cooked pulses | 120 / 8 / 0.5 / 2 | 150 | 100 |
| Vegetables | 30 / 2 / 0.2 / 40 | 200 | 300 |
| Fruit | 50 / 0.5 / 0.2 / 30 | 150 | 200 |
| Oil | 900 / 0 / 100 / 0 | 15 | 25 |

A totals: 815 g food; 840 kcal; 24.25 g protein; 17.35 g fat; 128 mg vitamin C; 150 g fruit; 200 g vegetables.

B totals: 825 g food; 795 kcal; 20.00 g protein; 27.10 g fat; 182 mg vitamin C; 200 g fruit; 300 g vegetables.

Per 1,000 kcal: A = 28.87 g protein, 20.65 g fat, 152.38 mg C, 178.57 g fruit, 238.10 g vegetables. B = 25.16 g protein, 34.09 g fat, 228.93 mg C, 251.57 g fruit, 377.36 g vegetables.

A has more protein per unit of energy; B has more vitamin C and fruit/vegetable grams per unit of energy. That describes the profiles; it does not establish an overall winner.

Missing-data check: if B’s vegetable vitamin C is unknown, its known C subtotal is 62 mg. Mass coverage is 525/825 = 63.64%; energy coverage is 705/795 = 88.68%. B’s full vitamin C total and rank must be withheld, not recorded as 62 mg or zero.

# 12. Readiness gates and practical handoff

The register is geographically complete and now structurally normalised. It is not quantitatively complete. The next enrichment stage can use stable country-line IDs and the companion specification to fill the explicit gaps without losing the original evidence.

| Gate | Pass condition | Current result |
|---|---|---|
| Identity / scope | Every ISO entry and source food label preserved; demos separated from published examples. | 249 entries; 3,230 lines mapped to provisional concepts. |
| Quantity / state | Complete basket quantities, population/period, edible fractions and preparation basis. | Not complete for any country basket. |
| Composition | State-specific nutrient matches with definitions, dates, rights and metric-level coverage. | No verified matches assigned in this addendum. |
| Comparison | Aligned cohort/denominators; complete required data; estimates and uncertainty disclosed. | No nutritional country ranking enabled. |
| Product / menu | Resolved market/product or venue/recipe/serving; ingredients and current evidence. | Contract defined; live records and APIs unverified. |
| Qualification | Applicable dietary/supplier rule evaluated against current, scoped evidence. | Fields and evaluation states defined; credentials unverified. |

Handoff acceptance checks: all 249 ISO codes appear exactly once; all 2,523 demo and 707 published-example lines retain their original wording; no source example is promoted into an official full basket; unresolvable alternatives stay explicit; missing numeric data is null, never zero.

Before enabling calculations, validate unit conversions, compatible nutrient definitions, mass/recipe balances, group fractions, raw/cooked handling and incomplete-data gates. Before selecting products, verify identifiers, serving/pack quantities, current claims, supplier scope and licence permissions.

Suggested first operational pilot: choose a few well-documented markets, extract complete quantities from the cited primary sources, review local food matches, then validate the full product/menu/qualification path. Expand the same contract across all 249 entries without manufacturing data for gaps.
